

|                                           | Estimate | 95% set        | $TS_{\min}$ |
|-------------------------------------------|----------|----------------|-------------|
| True credits, $E[\tau_P M]$               | 1,875    | [1,589, 2,137] | 22.3        |
| Potential revenue, $E[P]$                 | -328     | [-590, -42]    | 22.3        |
| Increase in net refunds, $L/ P $          | 0.218    | [0.114, 1.306] | 20.7        |
| Loss / sales tax on sales: interior firms | 4.7%     | [2.8%, 7.1%]   | 20.2        |
| (A) evader industries                     | 4.1%     | [2.8%, 5.5%]   | 20.6        |
| (B) all firms                             | 1.5%     | [1.1%, 3.1%]   | 18.9        |

ELVIS interior firms, real pesos per firm-year, current rates.  $L = \tau_P(1 - q(e))e$ ;  $P = t1/p_{gdp} - \tau_P M$ ;  $R = P - L$ . The  $E[P]$  set follows from the  $E[\tau_P M]$  set because  $t1$  is observed (mean 1,547). Loss  $L$  as a share of the sales tax owed on sales: (A) adds the trimmed firms' tax, (B) every firm's tax in the sample; their loss is set to zero, so (A) and (B) are lower bounds. Each set is the union of the values accepted over several solver runs. Conservative test,  $TS \leq \chi^2_{18,.95} = 28.87$ .
