Real pesos per firm-year, ELVIS interior firms (12,050 firm-years). Net sales-tax revenue = sales tax on sales minus expected claimed purchase credits. 95% set: conservative test, $TS \leq \chi^2_{18,.95} = 28.87$. True materials respond: the materials first-order condition with the two tax rates, capital, labour and productivity fixed. True M : mean change in true materials; tax from output: mean change in the sales tax on sales from the output response. Both come from the data alone. −27.5% is the smallest cut, on a finer grid, whose 95% set excludes zero (true materials respond only).
