

CV-adjusted R, conservative test (Theorem F.1) – all 15 . points, fully bisected

Blue = passes at 95% ($\Delta=18.3$); gray $\times$ = rejected. Gray band = $\Delta=0$'s own passing interval, for visual reference.

Crossing found: Delta=-8% is the smallest tax cut statistically distinguishable from Delta=0 (sequential search, see Research-log/log.md). Cuts -1% to -7% still overlap the Delta=0 band. Increases ($\geq +0.5\%$) separate cleanly.
