Millions of real pesos, sum over all firm-years in the sample (1981–1991), true materials respond. (A) evader industries: the ELVIS interior firms plus the 0.5% trimmed from estimation; (B) all firms: (A) plus every other firm in the sample. Firms outside the ELVIS sample are treated as reporting their true materials, so their claimed deductions and gross sales-tax revenue change only through the rate and the response of their materials. The 95% sets (conservative test, $TS \leq \chi^2_{18,.95} = 28.87$) come from the interior firms; the other firms add a known amount.
