Evasion-corrected columns use the first stage on the log materials share net of sales taxes; $\hat{\beta}$ is the corporations' first-stage estimate, common to the three evasion-corrected columns; below it, its 95% test-inversion regions from the corporations' share moment (the production-function moments are exactly identified given β and profiled): sharp (χ^2_1) and conservative (χ^2_5). Point estimates: the minimum of the test-inversion statistic, with the covariance of the moments re-estimated at each candidate (α_K, α_L), the statistic whose regions are shown. $\tilde{\mathcal{W}}_{it-2}$ (the headline) and m^*_{it-1}: one instrument each (exactly identified, statistic zero at the estimate); below them, the projections of the 95% test-inversion regions for (α_K, α_L) (0.005 grid over $[0, 1]^2$): sharp (χ^2_2, credit for profiling γ_0, γ_1) and conservative (χ^2_4). Joint efficient GMM: both instruments together; sharp (χ^2_3) and conservative (χ^2_5) regions. GNR and OLS: uncorrected estimates on the same sample (GNR's share regression on the log materials share net of sales taxes). (· or ·): the bound of the parameter space (0 or 1) is not rejected. Industries: the five largest, by share of output, where overreporting is detected at the 1% level and the variance of the unincorporated firms' residual is at least the corporations' (the condition the deconvolution requires; Beverages, 313, fails it) (all nine in Appendix E).
